

NSD & delta Elevation

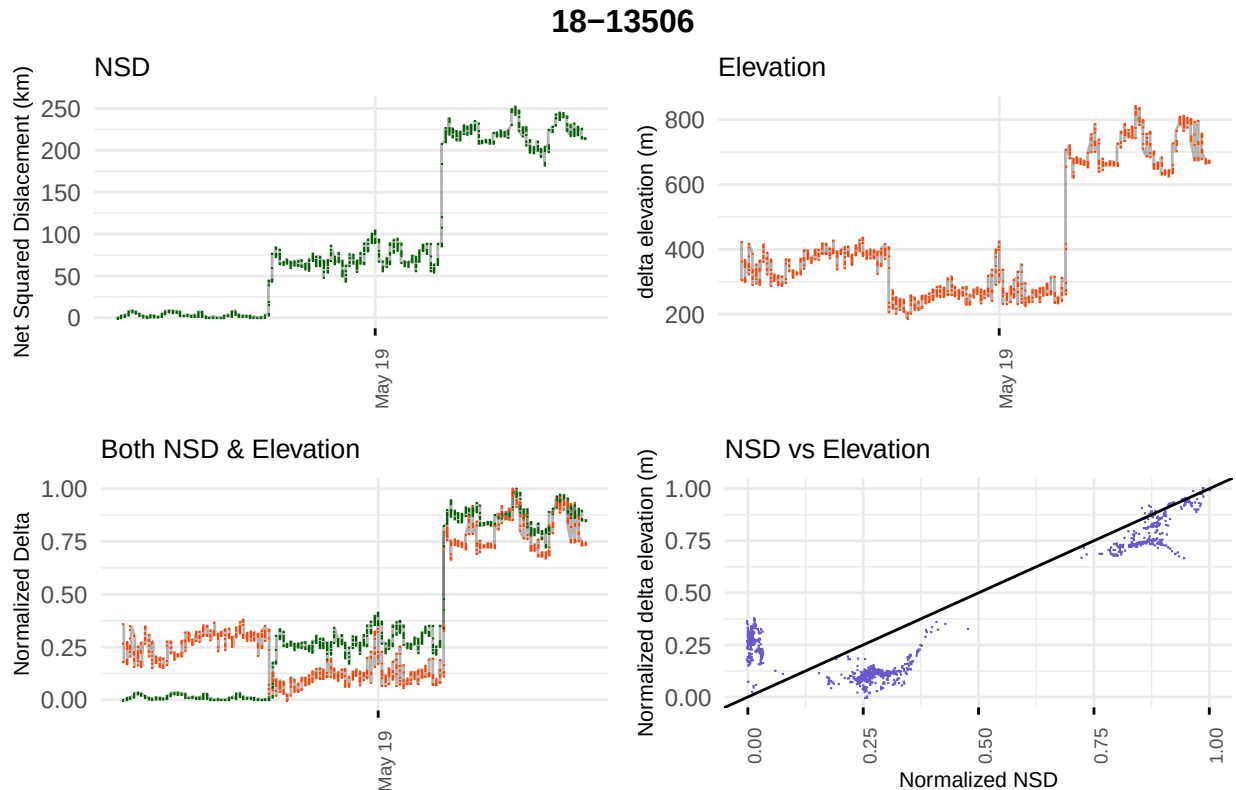

2026-06-16

Note that net squared displacement is measured from the initial collaring location.

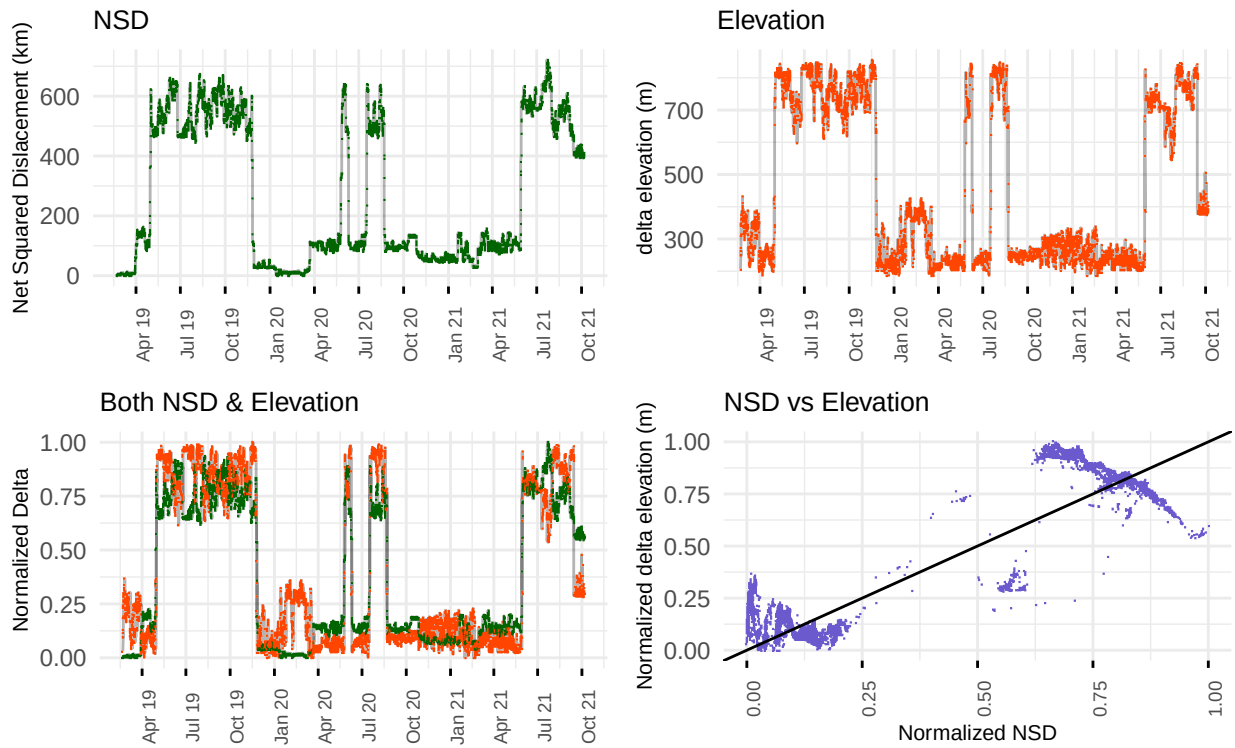

Delta elevation is calculated as an elk's current elevation minus the minimum elevation of that elk. Therefore, all elk are measured from a baseline elevation of 0 meters for the purposes of plotting. This is done to account for elk that live close to shore, and therefore have a lower baseline elevation, versus elk that live more in the interior, which has a higher baseline elevation, even when that elk is in a valley bottom.

NSD and delta elevation are both normalized to run from 0 to 1 for the plots where both NSD and elevation show up simultaneously, to ensure they both share the same y-axis. *This erases the magnitude of change.* Only use these plots to see if the pattern of movement (NSD vs delta elevation) lines up.

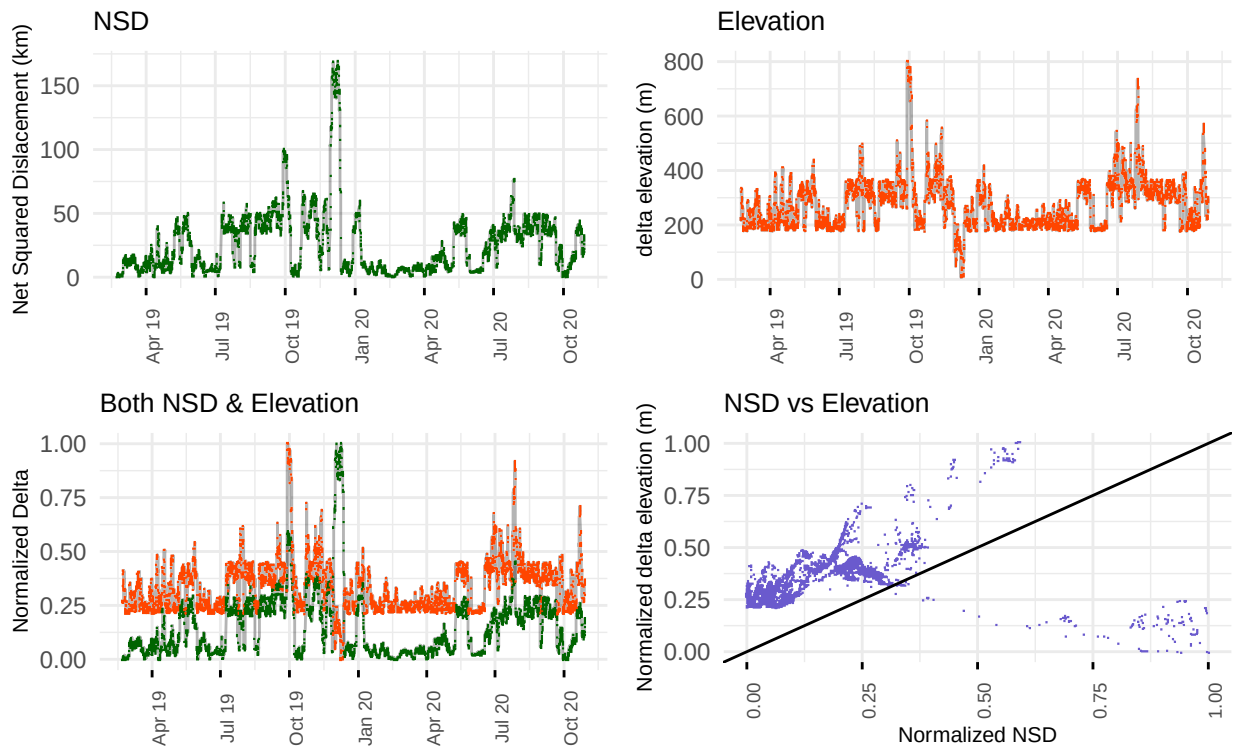

Finally, for the NSD vs Elevation plots, I don't know if these are useful at all, but I threw them in thinking points falling along a 1:1 line indicates that NSD and delta elevation are tightly correlated.
